

Calculate $\mathrm{i}_{1}$.

## Calculate $i_{1}$.

The 10 mA source provides all the current flowing through the $200 \Omega$ in parallel with $800 \Omega$. (Note that 10 mA flows through the 300ohm from left to right so 10 mA will divide through the 200 and 800ohm). Thus, the current divider formula gives the value of i1:

$$
\begin{gathered}
\mathrm{i}_{1}=\frac{10 \mathrm{~m}(800)}{(800+200)}=\frac{10 \mathrm{~m}(800)}{1 \mathrm{k}} \\
\mathrm{i}_{1}=8 \mathrm{~mA}
\end{gathered}
$$

## Calculate $\mathrm{V}_{1}$.

If we follow the wires in the circuit, the $12 \Omega$ is in series with the $3 \Omega$, and the 5 V source is in series with 15 V which is across (highlighted). Thus, the value of $V_{1}$ is given by the voltagedivider formula:

$$
\begin{gathered}
\mathrm{V}_{1}=\frac{10(3)}{12+3}=\frac{30}{15} \\
\mathrm{~V}_{1}=2 \mathrm{~V}
\end{gathered}
$$

3. Find the value of total resistance between terminals $\mathbf{a}$ and $\mathbf{b}$.

| $7 \mathrm{~K} \Omega$ | Rab=3k+7k+(1k\||1k)||2k |
| :---: | :---: |
| $1 \mathrm{~K} \Omega$ | $R a b=10 k+\frac{(1 k)(1 k)}{1 k+1 k} \\| 2 k$ |
| m | $R a b=10 k+2 k \\| 2 k$ |
| $2 \mathrm{k} \Omega$ | Rab $=10 k+\frac{(2 k)(2 k)}{2 k+2 k}$ |
|  | Rab $=10 k+1 k$ |
|  | $R a b=11,000 \Omega$ |

4. 

Sol' N : a) The voltage drops and currents may be measured in one of two directions for each resistor so long as we follow the passive sign convention. One such consistent labeling is shown below.

Derive an expression for $v_{1}$. The expression must not contain more than the circuit parameters $i_{\mathrm{a}}, v_{\mathrm{d}}, R_{1}$, and $R_{2}$.

We observe that no components are in series and carrying the same current. (This is always a necessary thing to check for, however, as we need such equations when there are components in series.)

Looking for voltage-loops, we find that only the lower loop avoids the current source.

$$
i_{1} R_{1}-i_{2} R_{2}-v_{\mathrm{a}}=0 \mathrm{~V}
$$

A current summation at the left node gives a second equation for $i_{1}$ and $i_{2}$ :

$$
-i_{\mathrm{a}}+i_{2}+i_{1}=0 \mathrm{~A}
$$

Solving this equation for $i_{2}$ in terms of $i_{1}$ yields the following result:

$$
i_{2}=i_{\mathrm{a}}-i_{1}
$$

Substituting for $i_{2}$ in the previous equation yields an equation in terms on only $i_{1}$ :

$$
i_{1} R_{1}-\left(i_{\mathrm{a}}-i_{1}\right) R_{2}-v_{\mathrm{a}}=0 \mathrm{~V}
$$

or

$$
i_{1}\left(R_{1}+R_{2}\right)=v_{\mathrm{a}}+i_{\mathrm{a}} R_{2}
$$

or

$$
i_{1}=\frac{v_{\mathrm{a}}+i_{\mathrm{a}} R_{2}}{R_{1}+R_{2}}
$$

By Ohm's law, $v_{1}=i_{1} R_{1}$.

$$
i_{1}=\left(v_{\mathrm{a}}+i_{\mathrm{a}} R_{2}\right) \frac{R_{1}}{R_{1}+R_{2}}
$$

5. Derive an expression using the circuit in Problem \#4 above for the power through R2 resistor. The known values are $\mathrm{i}_{\mathrm{a}}, \mathrm{V}_{\mathrm{a}}, \mathrm{R}_{1}$, and $\mathrm{R}_{2}$.
$i_{2}=i_{a}-i_{1} \quad$ power $=i_{2} \cdot i_{2} \cdot R_{2}=\left(i_{a}-i_{1}\right)^{2} R_{2}=i_{a}^{2} R_{2}-2 i_{a} i_{1} R_{2}+i_{1}^{2} R_{2}=$
power $==i_{a}^{2} R_{2}-2 i_{a}\left(v_{a}+i_{a} R_{2}\right) \frac{R_{1}}{R_{1}+R_{2}} R_{2}+\left(v_{a}+i_{a} R_{2}\right)^{2}\left(\frac{R_{1}}{R_{1}+R_{2}}\right)^{2} R_{2}$
6. 

Derive the expression for $\mathrm{V}_{1}$ containing not more than circuit parameters $\alpha, \mathrm{R}_{1}, \mathrm{R}_{2}, \mathrm{R}_{3}, \mathrm{~V}_{\mathrm{a}}$, and $\mathrm{i}_{\mathrm{a}}$.
The above circuit is labeled with current directions and polarity. Using these labeled currents, there are 3 voltage loops:

$$
\begin{aligned}
& +V_{1}+\alpha V_{1}-i_{3} R_{3}-V_{a}=0 \\
& +i_{1} R_{1}+i_{2} R_{2}-i_{3} R_{3}-V_{a}=0 \\
& \alpha V_{1}-i_{2} R_{2}=0
\end{aligned}
$$

Taking a current summation:

$$
\begin{aligned}
& +\mathrm{i}_{\mathrm{a}}-\mathrm{i}_{1}-\mathrm{i}_{3}=0 \\
& \mathrm{i}_{3}=\left(\mathrm{i}_{\mathrm{a}}-\mathrm{i}_{1}\right)
\end{aligned}
$$

Taking the first equation from the voltage loops and plugging in the above value for $\mathrm{i}_{3}$ :

$$
V_{1}(\alpha+1)-i_{a} R_{3}+i_{1} R_{3}-V_{a}=0
$$

Using Ohm's Law in this equation for $\mathrm{V}_{1}$ :

$$
\begin{aligned}
& V_{1}=i_{1} R_{1} \\
& i_{1} R_{1}(\alpha+1)+i_{1} R_{3}=i_{a} R_{3}+V_{a} \\
& V_{1}=i_{1} R_{1}=\left[\frac{i_{a} R_{3}+V_{a}}{R_{3}+R_{1}(\alpha+1)}\right] R_{1}
\end{aligned}
$$

7. Using the circuit shown in Problem \#6, derive an expression for the power through R2. The known values are $\alpha, i_{a}, V_{a}, R_{1}, R_{2}$ and $R_{3}$.

Using the value found in \#6 and solving for the Power:
$\mathrm{P}=\mathrm{i}_{1} \times \mathrm{V}_{1}=\left[\frac{\left(\mathrm{i}_{\mathrm{a}} \mathrm{R}_{3}+\mathrm{V}_{\mathrm{a}}\right)}{\left(\mathrm{R}_{3}+\mathrm{R}_{1}(\alpha+1)\right)}\right]^{2} \mathrm{R}_{1}$
8.

Derive an expression for $i_{3}$. The expression must not contain more than the circuit parameters $\alpha, v_{\mathrm{a}}, R_{1}, R_{2}$, and $R_{3}$. Note: $\alpha>0$.

Sol'n: We add to the circuit diagram labels that are consistent with the passive sign convention:

We look for components in series and find that $R_{2}$ and $R_{3}$ are in series.
Turning to voltage loops, we have valid voltage loops on the left side and right side. The left side yields the following equation:

$$
v_{\mathrm{a}}-i_{\mathbf{x}} R_{1}-\alpha i_{\mathbf{x}}=0 \mathrm{~V}
$$

We can solve this equation for $i_{i}$ immediately:

$$
i_{\mathrm{x}}=\frac{v_{\mathrm{a}}}{R_{1}-\alpha}
$$

The right side yields the following equation:

$$
\alpha i_{\mathrm{z}}-i_{3} R_{2}-i_{3} R_{3}=0 \mathrm{~A}
$$

Using the value of $i_{2}$ from above, we can solve for $i_{3}$ :

$$
i_{3}=\frac{\alpha v_{\mathrm{a}}}{\left(R_{1}-\alpha\right)\left(R_{2}+R_{3}\right)}
$$

9. 

The op-amp operates in the linear mode. Using an appropriate model of the opamp, derive an expression for $v_{\mathrm{o}}$ in terms of not more than $i_{\mathrm{a}}, v_{\mathrm{d}}, R_{1}$, and $\mathrm{R}_{2}$.

Sol'n: We first remove the op-amp and assume the op-amp output voltage has the value necessary to make the voltage drop across the op-amp inputs equal zero volts. One possible way of labeling the resulting circuit, consistent with the passive sign convention, is shown below.

Looking first for components in series that carry the same current, we find only $R_{2}$ and $v_{0}$ and $v_{\mathrm{a}}$, which is if little help since we avoid defining a current for a voltage source.

We move on to voltage loops. We must use a loop that passes through $v_{\mathrm{i}}=0 \mathrm{~V}$, if possible. On the left, we have a voltage loop that skips $v_{\mathrm{a}}$ to pass through $R_{1}$ and then through $v_{\mathrm{i}}$.

$$
v_{\mathrm{a}}-i_{1} R_{1}+v_{\mathrm{i}}=0 \mathrm{~V}
$$

Note that we use Ohm's law to write $v_{1}$ as $i_{1} R_{1}$ and eliminate $v_{1}$ immediately. Since $v_{1}=0 \mathrm{~V}$, we may solve for $i_{1}$.

$$
\begin{equation*}
i_{1}=\frac{v_{\mathrm{a}}}{R_{1}} \tag{1}
\end{equation*}
$$

On the right side, we have a second voltage loop.

$$
\begin{equation*}
-v_{i}-i_{2} R_{2}-v_{0}=0 \mathrm{~V} \tag{2}
\end{equation*}
$$

Now we look for a node where we can do a current summation. The top node is the most obvious node where we might have three nonzero currents without having to define a current for a voltage source. (The node on the left side would also work if we observe that $i_{2}$ flows in $v_{\mathrm{a}}$.)

$$
\begin{equation*}
-i_{1}-i_{\mathrm{a}}+i_{2}=0 \mathrm{~A} \tag{3}
\end{equation*}
$$

Using the value of $i_{1}$ from (1), we can solve (3) for $i_{2}$ :

$$
i_{2}=i_{\mathrm{a}}+\frac{v_{\mathrm{a}}}{R_{1}}
$$

Using this value for $i_{2}$ and using $v_{\mathrm{O}}=0 \mathrm{~V}$ we can solve (2) for $v_{\mathrm{a}}$ :

$$
v_{0}=-i_{2} R_{2}=-\left(i_{\mathrm{a}}+\frac{v_{\mathrm{a}}}{R_{1}}\right) R_{2}
$$

The op-amp operates is in the linear mode. Using an appropriate model of the op-amp, derive an expression for $V_{o}$ in terms of not more than $i_{a}, R_{1}, R_{2}, R_{3}$, and $V_{a}$.

We first remove the op-amp and assume the op-amp output voltage has the value necessary to make the voltage drop across the op-amp inputs equal zero volts. One possible way of labeling the resulting circuit, consistent with the passive sign convention, is shown above (right).

Looking first for components in series that carry the same current, we see that $\mathrm{R}_{4}$ and $\mathrm{R}_{3}$ have equal but opposite currents:

$$
\mathrm{i}_{3}=-\mathrm{i}_{\mathrm{a}}
$$

Next, we look for voltage loops, making sure we use the 0 V drop across the op-amp inputs at least once. The small voltage loop shown on the diagram above yields the following Equation (using the current through $\mathrm{R}_{3}$ as $\mathrm{i}_{\mathrm{a}}$ :

$$
+\mathrm{V}_{\mathrm{a}}+\mathrm{i}_{\mathrm{a}} \mathrm{R}_{3}-\mathrm{V}_{\mathrm{o}}=0
$$

Solving for Vo:

$$
\mathrm{V}_{\mathrm{o}}=\mathrm{V}_{\mathrm{a}}+\mathrm{i}_{\mathrm{a}} \mathrm{R}_{3}
$$
