Imagine, if you will, a hydraulic device where the flow in a small pipe controls a valve in a larger pipe. The greater the flow in the small pipe the more it opens the valve in the large pipe. Take a look at the figure to the right. As an engineering student you should immediately see that this could be a useful device. One use might be as a flow-controlled on/off valve (switch). Or, depending on the flows and pressures involved, it could be used as an amplifier. That is, it could be used to make some hydraulic signal larger and more powerful. (A signal is a flow or pressure which conveys information and an amplifier is a device which increases the power of a signal.)
The electrical equivalent of this flow-controlled valve is a transistor. Specifically the NPN bipolar junction transistor (BJT). (There are other types.) The symbol for a transistor is shown below. Notice that it's a three-terminal device. That's because the control current (into the base) and the controlled current (into the collector) join together to form a single current out of the bottom (the emitter current). The valve drawn below is a more accurate analogy for the electrical transistor.

NPN transistor

A transistor has three terminals-- the base, the collector, and the emitter. The current flow from the collector to the emitter (through the transistor) is controlled by the current flow from the base to the emitter. A small base current can control a much larger collector current. Often they are related by a simple factor, called beta ( $\beta$ ). For a given base current, the transistor will allow $\beta$ times as much collector current. The key word here is allow. The transistor doesn't make the current flow-- some outside power source does that. It simply regulates the current like the valve above. Big power transistors usually have a $\beta$ s between 20 and 100. For little signal transistors, $\beta$ is usually between 100 and 400. Darlington transistors (really two transistors in one package) can have $\beta s$ in the 1000s.

A transistor can be used as a current controlled switch. When there's no base current, it's off, like an open switch. When there is a base current, it's on. If something outside of the transistor is limiting the collector current to less than $\beta$ times the base current then the transistor will turn on as much as it can, like a closed switch. A transistor that is off is operating in its "cutoff" region. A transistor that is fully on is operating in its "saturation" region. A transistor that is partially on is in active control of its collector current ( $\beta$ times the base current) and is operating in its "active" region. (Note the valve analogy has a problem with the "open" and "closed" terms.)
There are many types of transistors. PNP transistors work like the NPN transistors, except that all the currents and voltages are backwards. Field-effect transistors (FETs) are are controlled by voltage instead of current and come in many varieties. In this class we'll only work with NPN transistors.

Silicon diodes are made of two layers of doped silicon, a P layer is the anode and an N layer is the cathode. A P-N junction is a diode.

Bipolar junction transistors (BJTs) consist of three layers
 of doped silicon. The NPN transistor has a thin layer of $P$-doped silicon sandwiched between two layers of N -doped silicon. Each P-N junction can act like a diode. In fact, this is a fairly good way to check a transistor with an ohmmeter (set to the diode setting).

The base-emitter junction always acts like a diode, but because the base is very thin, it makes the other junction act like a controlled valve (you probably don' twant to know the details, so call it magic).

## Transistor Symbols

Notice the subscripts
$v_{B E}=v_{B}-v_{E}$
${ }^{\mathrm{v}} \mathrm{CE}={ }^{\mathrm{v}} \mathrm{C}^{-v^{2}} \mathrm{E}$

Replace $\mathrm{v}_{\mathrm{BE}}$ with $\mathrm{v}_{\mathrm{EB}}$ and
$v_{C E}$ with $v_{E C}$ in equations below

Modes or regions of operation
( $v_{B E}$ and $v_{C E}$ are approximate)

| $\frac{\text { Cutoff (off) }}{v_{B E}<0.7 \mathrm{~V}}$ | Active (partially on)  <br> $v_{B E} \simeq 0.7 \mathrm{~V}$  <br> $\mathrm{i}_{\mathrm{B}}=0$ $\mathrm{i}_{\mathrm{B}}>0$ <br> $\mathrm{i}_{\mathrm{C}}=0$ $\mathrm{v}_{\mathrm{CE}} \geq 0.2 \mathrm{~V}$ <br>  $\mathrm{i}_{\mathrm{C}}=\beta \mathrm{i}_{\mathrm{B}}=\alpha \mathrm{i}_{\mathrm{E}} \quad \alpha \simeq 1$ <br> controlled by the transistor. |
| :--- | :--- |

## The Transistor as a switch

Saturation (fully on)
$v_{B E} \simeq 0.7 \mathrm{~V}$
$\mathrm{i}_{\mathrm{B}}>0$
$\mathrm{v}_{\mathrm{CE}} \simeq 0.2 \mathrm{~V}$
$\mathrm{i}_{\mathrm{C}}<\beta \mathrm{i}_{\mathrm{B}} \begin{aligned} & \text { limited by something } \\ & \text { outside of the transistor }\end{aligned}$

One of the most common uses of a transistor is as a current-controlled switch. Transistor switches are the basis for all digital circuits, but that' s probably not where you' Il use the transistor. More likely, you' II want to control a high-current device, like a motor, with arintegrated-circuit output from a computer or logic circuit. The small integrated circuit won' t be able to supply enough current to run the motor, so you' II use a transistor to switch the larger current that flows through the motor. The input is hooked to the base of the transistor. (Often through a current limiting resistor, since $\mathrm{V}_{\mathrm{B}}$ will only be 0.7 V when the transistor is on.) A small $\mathrm{I}_{\mathrm{B}}$ can switch on the much larger $\mathrm{I}_{\mathrm{C}}$ and $\mathrm{V}_{\mathrm{CE}}$ can be as low as 0.2 V .
$\mathrm{V}_{\mathrm{CC}}$ : The terminal marked $\mathrm{V}_{\mathrm{CC}}$ above is just a circuit terminal hooked to a power supply, drawn in dotted lines here, but usually not shown at all. Power supply wires, like ground wires are often not shown explicitly on schematics. It makes the schematics a little less cluttered and easier to read.
Diode: If you' re switching an inductive load, like a motor, you should add a diode so that you' re not trying to switch off the motor current instantly. The diode (called a flyback diode when used like this) provides a path for the current still flowing through the motor when the transistor is switched off.

H-bridge: Of course, if you want to make the motor turn in both directions you' II need a more complex circuit. Look at the circuit at right, it' $s$ has the shape of an $H$, hence the name. If transistors $G_{1}$ and $Q_{4}$ are on, then the current flows as shown, left-to-right through the motor. If transistors $Q_{2}$ and $Q_{3}$ are on, then the current flows the other way through the motor and the motor will turn in the opposite direction. (The motor here is a permanent-magnet DC motor.) In my circuit, the top two transistors are PNPs, which makes the circuit more efficient. The H-bridge could also be made with all NPNs or with power MOSFET transistors.

An H -bridge requires four inputs, all operated in concert. To turn on $\mathrm{Q}_{1}$ and $\mathrm{Q}_{4}$,
 as shown, $\mathrm{V}_{\text {in } 1}$ would have to be low and $\mathrm{V}_{\text {in } 4}$ would have to be high. At the same time, the other two transistors would have to be off, so $\mathrm{V}_{\text {in2 }}$ would have to be high and $\mathrm{V}_{\text {in3 }}$ would have to be low.

## Linear Amplifiers

If the control circuit makes a mistake and turns on $Q_{1}$ and $Q_{3}$ (or $Q_{2}$ and $Q_{4}$ ) at the same time you' II have a toaster instead of a motor driver, at least for a short while.

The circuit at left requires only two inputs. Transistors $Q_{5}$ and $Q_{6}$ work as inverters, when their inputs are high, their outputs are low and vice-versa. The resistors are known as pull-up resistors.
The H-bridge should also include flyback diodes.

The objective of a linear amplifier is to output a faithful reproduction of an input signal, only bigger. A voltage amplifier makes the signal voltage bigger. A current amplifier makes the signal current bigger. Many amplifiers do both. All amplifiers should make the signal power bigger (depends somewhat on the load). Of course that means that they need a source of power, generally DC power from a battery or power supply. The signals are usually AC.
Unlike transistor switches, which operate in cutoff and saturation, linear amplifiers must operate in the active region.

## Important relations: (active region)

$$
\begin{aligned}
& { }^{{ }^{v}} \mathrm{BE}={ }^{v_{B}}-{ }^{\mathrm{v}} \mathrm{E}=0.7 \cdot \mathrm{~V} \quad{ }^{\mathrm{v}} \mathrm{CE}={ }^{\mathrm{v}} \mathrm{C}^{-}{ }^{\mathrm{v}} \mathrm{E}>0.7 \cdot \mathrm{~V}(\simeq 0.2 \mathrm{~V} \text { if saturated }) \\
& { }^{\mathrm{i}} \mathrm{C}=\beta \cdot \mathrm{i}_{\mathrm{B}}
\end{aligned}{ }^{\mathrm{i}_{\mathrm{C}}=\alpha \cdot \mathrm{i}_{\mathrm{E}} \simeq{ }^{\mathrm{i}_{\mathrm{E}}}}
$$

## Bias:

Outside of the active region the input (base current) doesn' t linearly control the output (collector current). To work as an linear amplifier, a transistor must operate in the active region. That means that the transistor must be turned on part way even when there' s no signal at al Look back at the valve analogy, if small fluctuations in the horizontal pipe flow ( $\mathrm{i}_{\mathrm{B}}$ ) should produce larger but similar fluctuations in the vertical pipe flow (ic), then there must always be some flow. If either flow ever stops, the horizontal pipe flow ( $\mathrm{i}_{\mathrm{B}}$ ) is no longer in control.
To work in the active region $\mathrm{i}_{\mathrm{B}}$ and $\mathrm{i}_{\mathrm{C}}$ must be positive for all values of the $A C$ signals. $\mathrm{i}_{\mathrm{B}}$ and $\mathrm{i}_{\mathrm{C}}$ must be biased to some positive DC value. We use capital letters $\left(I_{B}\right.$ and $\left.I_{C}\right)$ for these
$D C$ bias values and lower case letters ( $i_{b}$ and $i_{c}$ ) for the AC signals that will appear as fluctuations of these DC values

All voltages and currents can be shown in three different ways

|  | examples |  |  |
| :--- | :--- | :--- | :--- |
| $\mathrm{CAP}_{\mathrm{CAP}}$ | $\mathrm{V}_{\mathrm{B}}$ | $\mathrm{I}_{\mathrm{C}}$ |  |
| DC, Bias |  |  |  |
| $\mathrm{sm}_{\mathrm{sm}}$ | ${ }^{v_{b}}$ | $\mathrm{i}_{\mathrm{c}}$ | $A C$, signal |
| $\mathrm{sm}_{\mathrm{CAP}}$ | ${ }^{v_{B}}$ | $\mathrm{i}_{\mathrm{C}}$ | DC and AC Together |

The objective of bias then, is to partially turn on the transistor, to turn it, sort-of, half-way on. Now if I twiddle $\mathrm{i}_{\mathrm{B}}$, $\mathrm{i}_{\mathrm{C}}$ will show a similar, but bigger, twiddle-- that' s the whole idea. The transistor should never go into cutoff for any expected input signal, otherwise you' II geclipping at the output. Clipping is a form of distortion, where the output no longer looks like the input.
Furthermore, the transistor must not saturate. That will also cause clipping at the output.
Because $\beta$ can vary widely from transistor to transistor of the same part number and $V_{B E}$ changes with temperature, achieving a stable bias can be a bit of a problem. Usually an emitter resistor $\left(R_{E}\right)$ is needed to stabilize the bias.

## DC Analysis in the active region

DC analysis applies to both switching and bias, although the circuits we' II look at here will include an $R_{E}$ and we' Il be working in the active region, meaning they are bias circuits. The key to $D C$ analysis with an $R_{E}$ is usually finding $V_{B}$.
The circuit at right shows a typical bias arrangement. The equations below are for that circuit, adapt them as necessary to fit your actual circuit.

## If you can neglect $I_{B}$ :

Often in quick-and-dirty analysis you can neglect the base current, $\mathrm{I}_{\mathrm{B}}$. In that case:

$\mathrm{V}_{\mathrm{B}}=\mathrm{V}_{\mathrm{CC}} \cdot \frac{\mathrm{R}_{\mathrm{B} 2}}{\mathrm{R}_{\mathrm{B} 1}+\mathrm{R}_{\mathrm{B} 2}} \quad \quad \mathrm{~V}_{\mathrm{E}}=\mathrm{V}_{\mathrm{B}}-0.7 \cdot \mathrm{~V} \quad \mathrm{I}_{\mathrm{E}}=\frac{\mathrm{V}_{\mathrm{E}}}{\mathrm{R}_{\mathrm{E}}} \simeq \mathrm{I}_{\mathrm{C}} \quad \quad \mathrm{V}_{\mathrm{C}}=\mathrm{V}_{\mathrm{CC}}-\mathrm{I}_{\mathrm{C}} \cdot \mathrm{R}_{\mathrm{C}}$
This assumption is OK if: $\quad R_{B 1} \| R_{B 2} \ll \beta \cdot R_{E}$
Quick check: $\mathrm{R}_{\mathrm{B} 1}<10 \cdot \mathrm{R}_{\mathrm{E}} \quad$ and/or $\quad \mathrm{R}_{\mathrm{B} 2}<10 \cdot \mathrm{R}_{\mathrm{E}} \quad$ Should result in $<10 \%$ error if $\beta=100$

## If you can't neglect $I_{B}$ :

Then you need to make a Thevenin equivalent of the base bias resistors.

$$
\mathrm{V}_{\mathrm{BB}}=\mathrm{V}_{\mathrm{CC}} \cdot \frac{\mathrm{R}_{\mathrm{B} 2}}{\mathrm{R}_{\mathrm{B} 1}+\mathrm{R}_{\mathrm{B} 2}} \quad \quad \mathrm{R}_{\mathrm{BB}}=\frac{1}{\frac{1}{\mathrm{R}_{\mathrm{B} 1}}+\frac{1}{\mathrm{R}_{\mathrm{B} 2}}}
$$

From the base' s point-of-view, the emitter resistor will look $\beta+1$ ) times bigger than it really is. This is because $(\beta+1)$ times as much current flows through $R_{E}$ than into the base. We can ignore the fact that the current is bigger if we pretend that the resistor is bigger. That leads to the simplified circuit. (Usually we use $\beta$ as the factor rather than $(\beta+1)$, after all $\beta$ just isn' t that well known anyway.)

$I_{B}=\frac{V_{B B}-0.7 \cdot V}{R_{B B}+\beta \cdot R_{E}}$

$$
\mathrm{V}_{\mathrm{E}}=\mathrm{I}_{\mathrm{E}} \cdot \mathrm{R}_{\mathrm{E}} \simeq \mathrm{I}_{\mathrm{C}} \cdot \mathrm{R}_{\mathrm{E}}
$$

$\mathrm{V}_{\mathrm{B}}=\mathrm{V}_{\mathrm{E}}+0.7 \cdot \mathrm{~V}$
$\mathrm{V}_{\mathrm{C}}=\mathrm{V}_{\mathrm{CC}}-\mathrm{I}_{\mathrm{C}} \cdot \mathrm{R}_{\mathrm{C}}$
OR: $\quad V_{B}=I_{B} \cdot \beta \cdot R_{E}+0.7 \cdot V$

$$
\mathrm{V}_{\mathrm{E}}=\mathrm{V}_{\mathrm{B}}-0.7 \cdot \mathrm{~V} \quad \mathrm{I}_{\mathrm{E}}=\frac{\mathrm{V}_{\mathrm{E}}}{\mathrm{R}_{\mathrm{E}}} \simeq \mathrm{I}_{\mathrm{C}}
$$

$$
\mathrm{V}_{\mathrm{C}}=\mathrm{V}_{\mathrm{CC}}-\mathrm{I}_{\mathrm{C}} \cdot \mathrm{R}_{\mathrm{C}}
$$

## Examples, DC (Bias) Analysis

1) 

Given:
$\mathrm{V}_{\mathrm{B}}:=3 \cdot \mathrm{l}$, regardless of current into base
$\mathrm{V}_{\mathrm{CC}}:=20 \cdot \mathrm{~V} \mathrm{R}_{\mathrm{C}}:=10 \cdot \mathrm{k} \Omega \quad \mathrm{R}_{\mathrm{E}}:=2.7 \cdot \mathrm{k} \Omega$
Find $\mathrm{I}_{\mathrm{C}}, \mathrm{V}_{\mathrm{C}}, \mathrm{V}_{\mathrm{CE}}$, and $\mathrm{P}_{\mathrm{Q}}$ :
Solution:

$$
\begin{array}{ll}
\mathrm{V}_{\mathrm{E}}:=\mathrm{V}_{\mathrm{B}}-0.7 \cdot \mathrm{~V} & \mathrm{~V}_{\mathrm{E}}=2.3 \cdot \mathrm{~V} \\
\mathrm{I}_{\mathrm{E}}:=\frac{\mathrm{V}_{\mathrm{E}}}{\mathrm{R}_{\mathrm{E}}} & \mathrm{I}_{\mathrm{E}}=0.852 \cdot \mathrm{~mA} \simeq \mathrm{I}_{\mathrm{C}}:=\mathrm{I}_{\mathrm{E}} \\
\mathrm{~V}_{\mathrm{C}}:=\mathrm{V}_{\mathrm{CC}}-\mathrm{I}_{\mathrm{C}} \cdot \mathrm{R}_{\mathrm{C}} & \mathrm{~V}_{\mathrm{C}}=11.48 \cdot \mathrm{~V} \\
\mathrm{~V}_{\mathrm{CE}}:=\mathrm{V}_{\mathrm{C}}-\mathrm{V}_{\mathrm{E}} & \mathrm{~V}_{\mathrm{CE}}=9.18 \cdot \mathrm{~V}>0.2 \mathrm{~V}, \mathrm{OK}, \text { is in active region } \\
\mathrm{P}_{\mathrm{Q}}:=\mathrm{V}_{\mathrm{CE}} \cdot \mathrm{I}_{\mathrm{C}} & \mathrm{P}_{\mathrm{Q}}=7.82 \cdot \mathrm{~mW}
\end{array}
$$

2) 

$$
\mathrm{R}_{\mathrm{C}}:=\frac{\mathrm{v}_{\mathrm{CC}}-\mathrm{v}_{\mathrm{C}}}{\mathrm{I}_{\mathrm{C}}} \quad \mathrm{R}_{\mathrm{C}}=508 \cdot \Omega
$$

$$
\mathrm{I}_{\mathrm{RB} 2}:=\frac{\mathrm{V}_{\mathrm{B}}}{\mathrm{R}_{\mathrm{B} 2}} \quad \mathrm{I}_{\mathrm{RB} 2}=1 \cdot \mathrm{~mA}
$$

$\mathrm{V}_{\mathrm{CE}}:=\mathrm{V}_{\mathrm{C}}-\mathrm{V}_{\mathrm{E}} \quad \mathrm{V}_{\mathrm{CE}}=5.7 \cdot \mathrm{~V}>0.2 \mathrm{~V}$, OK , is in active region
Given: may neglect $\mathrm{I}_{\mathrm{B}}$

$$
\mathrm{V}_{\mathrm{CC}}:=10 \cdot \mathrm{~V} \quad \mathrm{~V}_{\mathrm{C}}:=7.0 \cdot \mathrm{~V}^{2} \quad \mathrm{R}_{\mathrm{B} 1}:=8 \cdot \mathrm{k} \Omega \quad \mathrm{R}_{\mathrm{B} 2}:=2 \cdot \mathrm{k} \Omega \quad \mathrm{R}_{\mathrm{E}}:=220 \cdot \Omega
$$

Find $V_{B}, V_{E}, I_{C}, R_{C}, V_{C E}, I_{R B 2}$, and $P_{Q}$ :
Solution:

$$
\mathrm{V}_{\mathrm{B}}:=\mathrm{V}_{\mathrm{CC}} \frac{\mathrm{R}_{\mathrm{B} 2}}{\mathrm{R}_{\mathrm{B} 1}+\mathrm{R}_{\mathrm{B} 2}} \quad \mathrm{~V}_{\mathrm{B}}=2 \cdot \mathrm{~V}
$$

$\mathrm{V}_{\mathrm{E}}:=\mathrm{V}_{\mathrm{B}}-0.7 \cdot \mathrm{~V} \quad \mathrm{~V}_{\mathrm{E}}=1.3 \cdot \mathrm{~V}$
$\mathrm{I}_{\mathrm{E}}:=\frac{\mathrm{V}_{\mathrm{E}}}{\mathrm{R}_{\mathrm{E}}} \quad \quad \mathrm{I}_{\mathrm{E}}=5.91 \cdot \mathrm{~mA} \quad \simeq \mathrm{I}_{\mathrm{C}}:=\mathrm{I}_{\mathrm{E}}$

$$
\mathrm{P}_{\mathrm{Q}}:=\mathrm{V}_{\mathrm{CE}} \cdot \mathrm{I}_{\mathrm{C}} \quad \mathrm{P}_{\mathrm{Q}}=33.68 \cdot \mathrm{~mW}
$$

Given: may NOT neglect $\mathrm{I}_{\mathrm{B}} \quad \beta:=150$
$\mathrm{V}_{\mathrm{CC}}:=12 \cdot \mathrm{~V} \quad \mathrm{~V}_{\mathrm{E}}:=2.0 \cdot \mathrm{~V} \quad \mathrm{~V}_{\mathrm{C}}:=6 \cdot \mathrm{~V} \quad \mathrm{I}_{\mathrm{RB} 2}:=0.1 \cdot \mathrm{~mA} \quad \mathrm{I}_{\mathrm{C}}:=4 \cdot \mathrm{~mA}$
Find $R_{E}, R_{C}, V_{B}, I_{B}, R_{B 2}$, and $R_{B 1}$ :
Solution:
$\mathrm{V}_{\mathrm{CE}}:=\mathrm{V}_{\mathrm{C}}-\mathrm{V}_{\mathrm{E}} \quad \mathrm{V}_{\mathrm{CE}}=4 \cdot \mathrm{~V} \quad>0.2 \mathrm{~V}$, is in active region
$\mathrm{I}_{\mathrm{E}} \simeq \mathrm{I}_{\mathrm{C}} \quad \mathrm{I}_{\mathrm{E}}:=\mathrm{I}_{\mathrm{C}} \quad \quad \mathrm{R}_{\mathrm{E}}:=\frac{\mathrm{V}_{\mathrm{E}}}{\mathrm{I}_{\mathrm{E}}} \quad \mathrm{R}_{\mathrm{E}}=500 \cdot \Omega$
$\mathrm{R}_{\mathrm{C}}:=\frac{\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{C}}}{\mathrm{I}_{\mathrm{C}}} \quad \mathrm{R}_{\mathrm{C}}=1.5 \cdot \mathrm{k} \Omega$
$\mathrm{V}_{\mathrm{B}}:=\mathrm{V}_{\mathrm{E}}+0.7 \cdot \mathrm{~V} \quad \mathrm{~V}_{\mathrm{B}}=2.7 \cdot \mathrm{~V}^{2} \quad \mathrm{I}_{\mathrm{B}}:=\frac{\mathrm{I}_{\mathrm{C}}}{\beta} \quad \quad \mathrm{I}_{\mathrm{B}}=0.027 \cdot \mathrm{~mA}$
$R_{\mathrm{B} 2}:=\frac{\mathrm{V}_{\mathrm{B}}}{\mathrm{I}_{\mathrm{RB} 2}} \quad \mathrm{R}_{\mathrm{B} 2}=27 \cdot \mathrm{k} \Omega \quad \quad \mathrm{R}_{\mathrm{B} 1}:=\frac{\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{B}}}{\mathrm{I}_{\mathrm{RB} 2}+\mathrm{I}_{\mathrm{B}}}$
$\mathrm{R}_{\mathrm{B} 1}=73.4 \cdot \mathrm{k} \Omega$

## AC Analysis of Common emitter (CE) amplifier

With an $\mathrm{R}_{\mathrm{E}}$, any AC signal applied to the base will then also appear just as big at the emitter (just lower by $0.7 \mathrm{~V} D \mathrm{D}$ ). The AC signal current through $R_{E}$, will be about the same as through $R_{C}$, so the $A C$ signal voltage across $R_{C}$ will be bigger than that across $R_{E}$ by the ratio of $R_{C} / R_{E}$. Recalling that the signal at the emitter is about the same as the signal at the base...
base to collector $A C$ gain $=\frac{v_{c}}{v_{b}}=\frac{R_{C}}{R_{E}}$

## Signals

If a capacitor is placed in parallel with $R_{E}$ then the effective $A C$ resistance in the emitter goes way down and the gain goes way up. In that case we need a way to estimate the AC resistance within the base-emitter junction itself.

$$
\text { This is called the small-signal emitter resistance: } \quad{ }^{r} e=\frac{25 \cdot \mathrm{mV}}{\mathrm{I}_{\mathrm{C}}}
$$

To find the gains when the input has a source resistance and the output is connected to a load resistor, the calculations become a little more complex. YOU DON' T NEED TO KNOW THE FOLLOWING MATERIAL.
$\mathrm{R}_{\mathrm{E}}$ is the DC resistance from emitter to ground
$R_{e}$ is the AC signal resistance from emitter to ground, may be zero
Input impedance: $\mathrm{R}_{\mathrm{i}}=\mathrm{R}_{\mathrm{B} 1}\left\|\mathrm{R}_{\mathrm{B} 2}\right\| \beta \cdot\left(\mathrm{r}_{\mathrm{e}}+\mathrm{R}_{\mathrm{e}}\right)$
Output impedance: $\mathrm{R}_{\mathrm{o}}=\mathrm{R}_{\mathrm{C}} \| \mathrm{r}_{\mathrm{o}}$ <-- $\mathrm{r}_{\mathrm{o}}$ Often neglected
AC collector resistance: $r_{c}=R_{C}\left\|R_{L}\right\| r_{o}$ $r_{0}$ is a characteristic of the transistor, and is often neglected
Voltage gain: $A_{v}=\frac{v_{o}}{v_{b}}=\frac{r_{c}}{r_{e}+R_{e}}$
OR: $\frac{v_{o}}{v_{s}}=\frac{R_{i}}{R_{S}+R_{i}} \cdot \frac{r_{c}}{r_{e}+R_{e}}$
Current gain: $A_{i}=\frac{i_{o}}{i_{i}}=\frac{r_{c}}{r_{e}+R_{e}} \cdot \frac{R_{i}}{R_{L}}=A_{v_{i}} \cdot \frac{R_{i}}{R_{L}}$

There are several other types of transistor amplifiers, but we won' tlook at them here.

If the $\mathrm{v}_{\mathrm{s}}$ signal were applied at the base, an AC signal would also appear at the collector. How much larger would it be? (Voltage gain).
base to collector AC gain $=\frac{\mathrm{v}_{\mathrm{c}}}{\mathrm{v}_{\mathrm{b}}}=\frac{\mathrm{R}_{\mathrm{C}}}{\mathrm{R}_{\mathrm{E}}}=8.33 \quad$ times bigger
